Neurons all the way down?

- What scale should we use?
	- Down to the synapse level?
	- **A** Neurons?
	- **Collective behavior of neurons?**
- For language processing, robustness and measurable macroscopic effects suggest a *large* number of neurons.
- Even for a large collection of neurons, we still have several options with respect to modeling.
	- Do we need detailed interactions between neurons? Are the shapes of the action potential relevant? Timing?
- Our goal is to reduce the number of features, yet retain a physical meaning.

Conditioning Axioms

- C1. For each stimulus s there is on every trial a unique conditioning distribution, called the smearing distribution, which is a probability distribution on the set of possible responses.
- C2. If a stimulus is sampled on a trial, the mode of its smearing distribution becomes, with probability θ , the point (if any) which is reinforced on that trial; with probability $1 - \theta$ the mode remains unchanged.
- C3. If no reinforcement occurs on a trial, there is no change in the smearing distribution of the sampled stimulus.
- C4. Stimuli which are not sampled on a given trial do not change their smearing distributions on that trial.
- C5. The probability θ that the mode of the smearing distribution of a sampled stimulus will become the point of the reinforced response is independent of the trial number and the preceding pattern of occurrence of events. **K ロ ▶ K 伊 ▶ K** Ω

[SR Theory](#page-6-0)

General comments on SR theory - I

- (i) \mathbb{Z}_n sums up previous conditioning and does not represent a computation on trial n;
- (iii) S_n (experimentally unobserved sampling of stimuli) uses an assumption about the number of stimuli being sampled in an experiment (usually uniform);
- (iii) X_n represents the first brain computation in the temporal sequence on a trial for the stochastic model; this computation selects the actual response on the trial from the conditioning distribution $k_s(x|z_{s,n})$, where s is the sampled stimulus on this trial $(S_n = s)$;

イロト イ押 トイヨ トイヨ トーヨ

General comments on SR theory - II

- (iv) Y_n is the reinforcement random variable whose distribution is part of the experimental design;
- (v) Z_{n+1} summarizes the assumed brain computations that often change at the end of a trial the state of conditioning of the stimulus s sampled on trial n ; in our stochastic model, this change in conditioning is represented by a change in the mode $z_{s,n}$ of the distribution $K_s(x|z_{s,n})$.

 Ω

- S1. Exactly one stimulus is sampled on each trial.
- S2. Given the set of stimuli available for sampling on a given trial, the probability of sampling a given element is independent of the trial number and the preceding pattern of occurrence of events.

 Ω

4 n → 4 fil

R1. The probability of the response on a trial is solely determined by the smearing distribution of the sampled stimulus.

How to represent responses with few oscillators?

• Each neural oscillator's dynamics can be described by the phase, φ .

$$
s(t) = A_s \cos \varphi_s(t) = A_s \cos (\omega t),
$$

\n
$$
r_1(t) = A_1 \cos \varphi_{r_1}(t) = A \cos (\omega t + \delta \varphi),
$$

\n
$$
r_2(t) = A_2 \cos \varphi_{r_2}(t) = A \cos (\omega t + \delta \varphi - \pi).
$$

\n
$$
I_1 \equiv \left\langle (s(t) + r_1(t))^2 \right\rangle_t = A^2 (1 + \cos (\delta \varphi)).
$$

\n
$$
I_2 \equiv \left\langle (s(t) + r_2(t))^2 \right\rangle_t = A^2 (1 - \cos (\delta \varphi)).
$$

• A response is the balance between the strengths I_1 and I_2 ,

$$
b = \frac{l_1 - l_2}{l_1 + l_2} = \cos(\delta \varphi)
$$

4 ロト 4 母

Kuramoto Equations

If no interaction, $\varphi_i = \omega_i t + \delta_i$, and

 $\dot{\varphi}_i = \omega_i.$

If we have a weak interaction, then

$$
\dot{\varphi}_i = \omega_i - \sum_{j \neq i} A_{ij} \sin (\varphi_i - \varphi_j).
$$

 QQ

∍

(ロ) (母)

Encoding responses

• To encode responses, we need to modify

$$
\dot{\varphi}_i = \omega_i - \sum_{j \neq i} A_{ij} \sin (\varphi_i - \varphi_j)
$$

to include angles, i.e.,

$$
\dot{\phi}_i = \omega_i + \sum A_{ij} \sin (\phi_j - \phi_i + \delta \varphi_{ij}).
$$

 $\dot{\phi}_i = \omega_i + \sum \left[A_{ij} \sin \left(\phi_j - \phi_i \right) + B_{ij} \cos \left(\phi_j - \phi_i \right) \right] .$

 $\mathbb{B} \rightarrow \mathbb{R} \oplus \mathbb{R} \rightarrow \mathbb{R} \oplus \mathbb{R}$

 Ω

(ロ) (伊)

Encoding responses

• To encode responses, we need to modify

$$
\dot{\varphi}_i = \omega_i - \sum_{j \neq i} A_{ij} \sin (\varphi_i - \varphi_j)
$$

to include angles, i.e.,

$$
\dot{\phi}_i = \omega_i + \sum A_{ij} \sin (\phi_j - \phi_i + \delta \varphi_{ij}).
$$

$$
\dot{\phi}_i = \omega_i + \sum [A_{ij} \sin (\phi_j - \phi_i) + B_{ij} \cos (\phi_j - \phi_i)].
$$

Reinforcing oscillators

• During reinforcement:

$$
\dot{\phi}_i = \omega_i + \sum [A_{ij} \sin (\phi_j - \phi_i) + B_{ij} \cos (\phi_j - \phi_i)]
$$

+ $K_0 \sin (\varphi_E - \varphi_i + \delta_{E_i}).$

$$
\frac{dk_{ij}^E}{dt} = \epsilon (K_0) [\alpha \cos (\varphi_i - \varphi_j) - k_{ij}],
$$

$$
\frac{dk_{ij}^I}{dt} = \epsilon (K_0) [\alpha \sin (\varphi_i - \varphi_j) - k_{ij}^I].
$$

 \Rightarrow B $2Q$

 $2Q$

∍

- • For two stimulus oscillators, s_1 and s_2 , and two response oscillators, r_1 and $r₂$.
- We select couplings between oscillators such that X is selected 60% of the time if s_1 is active, and 50% of the time if s_2 is active.
- By selecting the couplings between s_1 and s_2 , we can control the degree of synchronicity between then.
- If s₁ and s₂ are activated, we can have interference between s_1 and s₂.
- In such cases, X is selected less than 40% of the time.

(ロ) (母)

- A small number of phase oscillators may be used to model a continuum of responses (with results similar to SR theory).
- The model is simple enough such that we can easily understand physically how responses are selected via inhibitory and excitatory couplings.
- Interference may help us understand how complex neural networks have "quantum-like" dynamics.
